Hi Javier - If you wanted to test susceptibility of a component via the noise that is conducted/coupled on the wires into the component, you don't even need an EMI enclosure (it may be helpful, but we do testing all the time without one. Reference the conducted susceptibility test setup below:

If you wanted to test the radiated susceptiblity, you would need an EMI enclosure that you can radiate a set amount of noise/energy. You can get creative, and size is a consideration but with RF absorbing foam, it is possible:
